The 6 lines you just drew are the sides of the regular hexagon. (See Figure 2). (See Figure 2). A hexagon is the only case in which a polygon's sides will exactly equal the radius but, by using a compass, a ruler and the calculator below, you can construct regular polygons with any number of sides.

Constructing Regular Polygons

Some regular polygons are easy to construct with compass and straightedge; other regular polygons are not constructible at all. The ancient Greek mathematicians knew how to construct a regular polygon with 3, 4, or 5 sides, : p. xi and they knew how to construct a regular polygon with double the number of sides of a given regular polygon.

The radius of the incircle is the apothem of the polygon. (Not all polygons have those properties, but triangles and regular polygons do). Breaking into Triangles. We can learn a lot about regular polygons by breaking them into triangles like this: Notice that: the "base" of the triangle is one side of the polygon.

A regular polygon is a polygon that is equiangular and equilateral. This means that all its angles are the same measure and all its sides are the same length. The most basic example of a regular polygon is an equilateral triangle, a triangle with three congruent sides and three congruent angles. Squares are also regular polygons, because all their angles are the same (90°) and all their sides ...

Constructible regular polygons Now, by the end of Book IV, Euclid has described how to construct many regular polygons. The regular 3-gon, known as the equilateral triangle, was constructed in I.1, while the regular 4-gon, known as the square, was constructed in I.46. In book IV, regular 5-gons and regular 6-gons have been constructed.

Most of the established procedures construct regular polygons whose sides are to be measured [6, 7], but a number of the methods construct regular polygons of predetermined side lengths [5]. As mentioned above, majority of the methods of constructing regular polygons are tailored to particular family.
