Chapter 7 Electronic Configurations and the Properties of Atoms - 3 - In this text, we will arbitrarily assign  $m_s = +\frac{1}{2}$  to electrons represented with an upward arrow (also called “spin up” electrons) and  $m_s = -\frac{1}{2}$  to electrons represented with a downward arrow (also called “spin down” electrons).

As you have learned, the electron configurations of the elements explain the otherwise peculiar shape of the periodic table. Although the table was originally organized on the basis of physical and chemical similarities between the elements within groups, these similarities are ultimately attributable to orbital energy levels and the Pauli principle, which cause the individual subshells to be ...

Chemical Properties Valence electrons are the outermost electrons and are involved in bonding. Chapter 7 Section 2 Similarity of valence electron configurations helps predict chemical properties. Groups 1A, 2A and 8A all have similar properties to other members of their respective groups.

The actual electron configuration may be rationalized in terms of an added stability associated with a half-filled ( $ns^1$ ,  $np^3$ ,  $nd^5$ ,  $nf^7$ ) or filled ( $ns^2$ ,  $np^6$ ,  $nd^{10}$ ,  $nf^{14}$ ) subshell. (In fact, this "special stability" is really another consequence of the instability caused by pairing an electron with another in the same orbital, as illustrated by Hund's rule.)

The electron configurations described in this chapter all refer to gaseous atoms in their ground states. An atom may absorb a quantum of energy and promote one of its electrons to a higher-energy orbital. When this happens, we say that the atom is in an excited state. The electron configurations of some excited atoms

We use Lewis symbols to describe valence electron configurations of atoms and monatomic ions. A Lewis symbol consists of an elemental symbol surrounded by one dot for each of its valence electrons: Figure 1 shows the Lewis symbols for the elements of the third period of the periodic table.
