Other reaction molding processes also use polymerization to solidify the molded piece; however, in thermoset injection molding, for example, reactants are heated to around 200 °C to activate the reac- tion.

September 8, 2014 By Jeffrey Gotro Leave a Comment. Isothermal curing can be investigated nicely using oscillatory parallel plate rheometry. It is suggested that disposable plates be used to facilitate sample removal from the rheometer at the conclusion of the curing run. When setting up the rheometer, the strain amplitude needs to be determined. In most cases, a strain amplitude in the range of 0.1-0.3% is adequate to get good torque response over the viscosity range of interest for thermosets.

Thermosetting resin rheology can be studied using both dynamic oscillatory tests and steady shear. The first section of the viscosity range of a thermoset can be characterized with steady shear measurements. There is a rapid increase in steady shear viscosity close to the gel point and it becomes unmeasurable.

In the last post we talked about isothermal cure rheology. This is a good way to look at the curing time, gelation time, and get an understanding of the viscosity temperature dependence, but most commercial thermoset processing methods are non-isothermal. Whether it is bulk molding compound (BMC) molding, prepreg lamination for composites, or integrated circuit [...]

The resin chemistry employed in polymer matrix composite materials can be divided into two types, thermoplastic and thermosetting. This distinction has a very large impact on the inherent recyclability of a composite material. Thermoplastic polymer matrices soften and melt with the application of heat.
